## 2020 WHEAT CROP REVIEW

### Weather and Crop Development

From extreme drought and harsh spring freezes, to an almost stress-free growing season; variability is the key word explaining the 2020 winter wheat growing season in Kansas. Different parts of the state were exposed to different levels of stresses, resulting in very different crop conditions and yield levels.

#### *Fall drought: Wheat needs (at least some) water to emerge*

While the majority of the state started out the 2020 wheat growing season with enough precipitation to get a good crop establishment, this was not the case for a large portion of southwest Kansas. Cumulative precipitation between September 1 and December 31, 2019, ranged from 0.84 inches in the far southwest corner of Kansas to as much as 18.71 inches in far southeast. The majority of the wheat growing region (namely central and western Kansas) received between 0.84 and about 7.5 inches of precipitation during this period. For southwest Kansas, this precipitation amount represents a deficit of about 3.5 to 6.4 inches as compared to the long-term normal precipitation for the period studied. With such a limited precipitation amount in the southwest, the wheat crop was not able to germinate and emerge during the fall in approximately eight counties west and south of Finney County. The southwest Kansas crop did not emerge until December 28, 2019, when amounts of up to 1.25 inches of precipitation occurred. While a spring-emerged winter wheat crop can still vernalize and produce grain, its yield potential is about half of a fall-emerged crop; so the wheat season in southwest Kansas already started with a reduced yield potential.

While the remainder of the state had enough precipitation to emerge in the fall, it is important to note that more and more wheat area is double-cropped after a summer crop every year, especially after soybeans in central Kansas and after corn in western Kansas. These cropping systems delay wheat sowing and decrease the time for wheat tillering in the fall. There was a striking difference in fall development as affected by sowing date in the 2020 wheat crop; with early-sown fields attaining up to 6–8 tillers by December while late-sown fields only had the main tiller and perhaps an additional, secondary tiller at the same time. This difference is important because the fall-developed tillers have a greater yield potential than spring-developed tillers. Nonetheless, the winter was mild (average temperature of 34.3°F as compared to the long-term mean 31.8°F), which allowed the wheat crop to tiller through the winter and, to a given extent, compensate for the delayed sowing in many cases.

#### *Expansion of area under drought stress during the spring*

While southwest Kansas was the most affected area by fall drought, the water deficit expanded to the northwest and north central parts of the state during winter and early spring. The cumulative precipitation between September 1, 2019, and May 18, 2020, ranged from 2.85 inches in southwest Kansas, to about 7.75 inches in northwest Kansas, and up to about 11 inches in north central Kansas. When compared to the long-term normal for these regions, these total precipitation amounts correspond to a deficit of as much as 7.2 inches in north central and parts of southwest Kansas. Wheat fields were showing signs of drought stress that ranged from rolling up of leaves added to a blue tint to the crop in the west-central part of the state; to as much as a very stunted crop with senescence of lower canopy and tiller loss in north central and especially southwest Kansas. Meanwhile, central and south central Kansas had a relatively moist winter and early spring, accumulating between 13 and 21 inches of precipitation during the same period. As compared to the long-term normal, these values correspond to a slight deficit of about 1 inch to as much as 5 inches above normal.

#### *Regional differences in spring development due to moisture and temperature regimes*

With good moisture availability and a mild winter, the spring development of the wheat crop started on an average date in south central Kansas, with the majority of the wheat varieties reaching first hollow stem sometime in mid-March. For southwest and north central Kansas, however, wheat development during early spring was delayed due to the dry conditions, leading to a significant difference in development at different parts of the state. The wheat crop was still reaching the first node in north central Kansas by the time the crop was already heading in south central and southeast Kansas.

#### *Stem frost further decreasing the yield potential*

The occurrence of frost events during the spring is not unusual for Kansas and, depending on the region of the state and on cropping system/sowing date, those freezes impacted the wheat crop in different ways. In particular, the week of April 13–17 had several frost events in which air temperatures dipped close to single digits in northwest Kansas, and below 24°F for at least a few hours in most areas of the state, with the exception of south central and southeast Kansas. The areas most affected by these cold temperatures were north central and northwest Kansas, where dry conditions exacerbated the negative impacts of

the cold spell. While the crop was mostly still between tillering (northwest) and jointing (north central) stages, which are more tolerant to cold temperatures than more advanced stages, temperatures were cold enough to cause severe tiller and leaf losses. These losses were more apparent in the late-sown crops, usually following soybeans in north central and corn in western Kansas, mostly due to a small canopy having less potential to buffer the cold temperatures, where individual fields had 50–75% of tiller loss. In earlier sown fields, the tiller loss was more in the 20–40% range, and the plants were developed enough to compensate for this loss with secondary tillers. With the freeze events happening in mid-April and no significant precipitation occurring in these locations until mid- to late-May, the dry conditions that followed the freeze events further hampered wheat development and decreased the crop's yield potential. While the crop was more advanced in central and south central Kansas, the temperatures were not nearly as cold and therefore the crop sustained no injury from the freeze. Thus, the area south of McPherson County through Cowley County, and west to Meade County, was likely showing the best yield potential for wheat in Kansas during the 2020 season.

#### *Grain filling period*

As the 2020 wheat crop went through the grain filling period, the occurrence of precipitation in the last ten days of May helped the crop in most of the state. The precipitation during this period ranged from 0.97 inches to 2.99 inches, which was enough rain for most of the state to ensure at least an average crop despite all the previously mentioned adversities. However, southwest Kansas only received 0.97 inches of precipitation, with a divisional average of only 7.04 inches for the September to May period. In fact, many dryland fields in the region were going through the grain fill period and were only about 10 inches tall. Another issue faced by the crop were warm temperatures during the grain filling. The first week of June brought extremely high temperatures across the entire state, with as many as 58 hours above 91°F. While the crop in southwest and south central Kansas were already in the late dough stages by that time, the crop in north central and northwest Kansas were still at the early stages of grain fill. Those temperatures were likely enough to decrease photosynthetic rates and consequently further reduce yields in those regions (Romulo Lollato, Kansas State University Extension Wheat Specialist; and Mary Knapp, Kansas State University Climatologist.)

#### **Diseases**

In general, wheat diseases had a relatively low impact on yields in 2020. The most widespread disease was stripe rust, affecting most wheat producing counties across the state. Although stripe rust was widespread, levels remained

trace in most fields, likely due to a late arrival of the pathogen and warmer late season conditions.

There were several fields in central and southeast Kansas that had higher than normal tan spot, *Septoria tritici* blotch, and *Stagonospora* leaf blotch, likely due to high build-up of those pathogens in residue and wet weather.

Leaf rust arrived late enough in the season that yield loss was minimal. Wheat streak mosaic, which has been very severe in some years, was limited to pockets of severely damaged farms in 2020. (Kelsey Andersen Onofre, Kansas State University Department of Plant Pathology.)

#### **Insects**

During fall, as planted wheat germinated, there were a few reports of armyworms reducing early stands. Most of these infestations seemed to come from areas of brome adjacent to wheat. Some areas were treated with insecticides as they exceeded the treatment threshold. Another insect pest that caused problems in the 2019–2020 season were army cutworms. Many fields, especially in south central and north central Kansas, had areas decimated by army cutworm larvae that developed over the fall/winter from eggs deposited in the fall of 2019. Army cutworms are an occasional pest that seem to be more common and widespread in those years with a relatively dry summer and wet fall.

Hessian flies were relatively common during the 2019–2020 wheat growing season. Reports indicated that several fields were decimated by Hessian fly infestations, to the extent they were actually lost to harvest.

There were also a few reports of wheat curl mite infestations. Wheat curl mites cause problems mainly when they vector some of the viruses that cause wheat streak mosaic disease. Destruction of volunteer wheat is still the best way to mitigate infestations of wheat curl mites and most other wheat pests. (Jeff Whitworth, Kansas State University Department of Entomology.)

#### **Harvest Statistics**

The Kansas Agricultural Statistics' July 10 estimate of the 2020 crop was 307 million bushels from 6.4 million acres, down 9% from last year's crop. Yield per harvested acre is expected to average 48 bushels, down 4 bushels from last year's final yield. (July 12, 2020, *Crops Report*, Kansas Agricultural Statistics.)

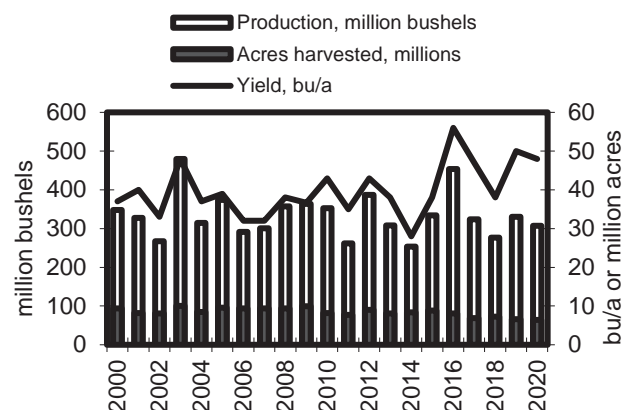

Figure 1. Historical Kansas wheat production

SY Monument achieved the number one spot as the top planted variety in Kansas after a gradual climb since 2015 with 9.7% of wheat planted acres. Zenda moved into the number two spot with 6.4%. WB Grainfield ranked third with 5.3%. Winterhawk claimed the fourth spot at 3.9%. Everest came in as the fifth most popular wheat variety with 2.9% after five consecutive years as number one. (March 2020, *Wheat Variety*, Kansas Agricultural Statistics.)

## 2020 Performance Tests

The Kansas Agricultural Experiment Station annually compares both new and currently grown varieties in the state’s major crop-producing areas. These performance tests generate unbiased performance information designed to help Kansas growers select wheat varieties suited for their area and conditions.

Site descriptions and management practices for each site are summarized in Table 3. One-year or one-location results can be misleading because of the possibility of

unusual weather or pest conditions. **Be sure to keep extenuating environmental conditions in mind when examining test results.** For more information please visit: [agronomy.ksu.edu/services/crop-performance-tests/index.html](http://agronomy.ksu.edu/services/crop-performance-tests/index.html).

## Varieties

Public varieties are selected for inclusion in the tests on the basis of several criteria. Most represent new or established varieties from Nebraska, Oklahoma, and Colorado with potential for successful use in Kansas. Some are included as long-term checks. Others are entered at the request of the originating institution.

Originators or marketers enter privately developed varieties voluntarily. Entrants choose both the entries and test sites. The 2020 entrants are listed in Table 1.

## Results and Variety Characterization

Results from Kansas tests are presented in Tables 4 through 11. Yields are reported as bushels per acre (60 lb/bu) and are adjusted to a moisture content of 13% where moistures were reported at harvest. Yields also are converted to percentages of the test average to speed recognition of the highest-yielding entries. Multi-year averages are presented for those varieties entered more than 1 year.

Additional information such as test weight, heading date, and plant height is helpful for fine-tuning variety comparisons. Planting varieties with a range of maturities helps minimize weather risks.

At the bottom of each table is the (0.05) least significant difference (LSD) for each column of replicated data. One can think of the LSD as a “margin of error” that shows how big the difference between two varieties must be for one to be 95% confident that the difference is real. The use of the LSD is intended to reduce the chance of overemphasizing small differences. Small variations in soil structure, fertility, water-holding characteristics, and other test-site characteristics can cause considerable yield variation among plots of one variety.

## Electronic Access

To access crop performance testing information electronically, visit the website at: [agronomy.ksu.edu/services/crop-performance-tests/index.html](http://agronomy.ksu.edu/services/crop-performance-tests/index.html).

## Research and Duplication Policy

When companies submit entries, permission is given to Kansas State University to test varieties and/or hybrids designated on the entry forms in the manner indicated in the test announcements. Seed submitted for testing should be a true sample of the seed being offered for sale.

All results from Kansas Crop Performance Tests belong to the University and the public and shall be controlled by the University to produce the greatest benefit to the public. Performance data may be used in the following ways: 1) Tables may be reproduced in their entirety, provided the source is referenced and data are not manipulated or reinterpreted; and 2) advertising statements by an individual company about the performance of its entries may be made as long as they are accurate statements about the data as published, with no reference to other companies' names or cultivars. In both cases, the following must be included with the reprint or ad citing the appropriate publication number and title: "See the official Kansas State University Agricultural Experiment Station and Cooperative Extension Service Report of Progress 1158, '2020 Kansas Performance Tests with Winter Wheat Varieties,' or the Kansas Crop Performance Test website, [agronomy.ksu.edu/services/crop-performance-tests/index.html](http://agronomy.ksu.edu/services/crop-performance-tests/index.html) for details. Endorsement or recommendation by Kansas State University is not implied."

Central KS Farmer's Field Lorraine (LR)	McCook silt loam Fallow	60	0	0	10/9/2019-6/30/2020	Fungicide applied. Early-maturing varieties were affected by freeze.
<b><u>South Central Dryland</u></b>						
South Central KS Farmer's Field McPherson (MC)	Crete silt loam Fallow	60	0	0	10/17/2019-6/26/2020	Fungicide applied. Early-maturing varieties were affected by freeze.
South Central KS Experiment Field Hutchinson (HU)	Funmar-Taver loam Canola	113	0	0	10/29/2019-6/30/2020	Fungicide applied. Generally good growing season.
South Central KS Farmer's Field Conway Springs (CW)	Sandy loam Fallow	40	0	0	10/16/2019-6/23/2020	Fungicide applied. Generally good growing season.
<b><u>Northwest Dryland</u></b>						
Research-Extension Center Hays (HA)	Harney silt loam Wheat	70	0	0	9/26/2019-6/29/2020	No fungicide applied. Freeze damage apparent in the spring.
Northwest Research-Extension Center Colby (CO)	Keith silt loam Fallow	60	0	0	9/23/2019-7/7/2020	No fungicide applied. Severe freeze damage in the spring.
Northwest Research-Extension Center Tribune (TR)	Richfield silt loam Fallow	112	40	0	10/7/2019-6/25/2020	Minimal freeze damage in the spring.
Northwest KS Farmer's Field Decatur (DC)	Harney clay loam Grain Sorghum	40	0	0	9/24/2019-7/8/2020	No fungicide applied.
<b><u>Southwest Dryland</u></b>						
Southwest KS Farmer's Field Larned (LA)	Harney clay loam Grain sorghum	80	0	0	9/29/2019-6/30/2020	Fungicide applied. Minimal freeze damage in the spring.
Southwest KS Farmer's Field Mullinville (MV)	Harney clay loam Grain Sorghum	80	0	0	10/8/2019-6/24/2020	Fungicide applied. Army cutworm grazing damage in April.
Southwest Research-Extension Center Garden City (GC)	Keith silt loam Wheat	60	0	0	10/9/2019-7/3/2020	No fungicide applied. Very dry conditions throughout season.
<b><u>Western Irrigated</u></b>						
Northwest Research-Extension Center Colby (CO)	Keith silt loam Fallow	100	0	0	9/23/2019-7/7/2020	No fungicide applied.
Southwest Research-Extension Center Garden City (GC)	Keith silt loam Corn	100	0	0	10/9/2019-7/3/2020	No fungicide applied.
Western KS Farmer's Field Healy, Lane County (LN)	Scott silt loam Fallow	90	0	0	9/24/2019-X	Abandoned: extensive freeze damage.
